1 Rings

1.1 Basic definitions

Definition 1.1. A ring is a set R equipped with two binary operations, namely addition and multiplication, such that

1. $(R, +)$ is an abelian group.
   (a) $a + b \in R$ for all $a, b \in R$.
   (b) $(a + b) + c = a + (b + c)$ for all $a, b, c \in R$.
   (c) $a + b = b + a$ for all $a, b \in R$.
   (d) There exists $0 \in R$ such that $a + 0 = a$ for all $a \in R$.
   (e) For each $a \in R$, there exists $-a \in R$ such that $a + (-a) = 0$.
2. $(R, \cdot)$ is a semi-group.
   (a) $a \cdot b \in R$ for all $a, b \in R$.
   (b) $(a \cdot b) \cdot c = a \cdot (b \cdot c)$ for all $a, b, c \in R$.
3. Multiplication distributes over addition.
   (a) $a \cdot (b + c) = (a \cdot b) + (a \cdot c)$ for all $a, b, c \in R$.
   (b) $(b + c) \cdot a = (b \cdot a) + (c \cdot a)$ for all $a, b, c \in R$.

Remark. The following properties follow immediately,

1. $0 \cdot a = 0$ for all $a \in R$.
2. $(-a) \cdot b = -(a \cdot b) = a \cdot (-b)$ for all $a, b \in R$.
3. $(na) \cdot b = n(a \cdot b) = a \cdot (nb)$ for all $a, b \in R$.

Example. The integers $\mathbb{Z}$ form a ring, under the usual addition and multiplication.

Example. All fields, for instance the rational numbers $\mathbb{Q}$ or the real numbers $\mathbb{R}$, are rings.

Example. The integers modulo n, namely $\mathbb{Z}/n\mathbb{Z}$, form a ring.

Example. If R is a ring, then the algebra of polynomials $R[X]$ with coefficients from R form a ring.

Example. If R is a ring, then the $n \times n$ matrices $M_n(R)$ with entries from R form a ring.

Definition 1.2. If R is a ring and $(R, \cdot)$ is a monoid i.e. has an identity, then this identity is unique and called the unity of the ring R. Such a ring R is called a unit ring. Note that we typically demand that this identity is distinct from the zero element.

Example. The even integers $2\mathbb{Z}$ form a ring, but do not contain the identity.

Example. The trivial ring $\{0\}$ is typically not considered to be a unit ring, since must serve as the additive identity as well as the multiplicative identity.

Definition 1.3. If R is a ring and $(R, \cdot)$ is commutative, then R is called a commutative ring.

Definition 1.4. Let R be a unit ring. An element $a \in R$ is called a unit if there exists $b \in R$ such that $a \cdot b = 1 = b \cdot a$. This $b \in R$ is unique, and denoted by a^{-1}.

Example. The units in $\mathbb{Z}$ are $\{1, -1\}$.

Definition 1.5. Let R be a ring, and let $S \subseteq R$. We say S is a subring of R if the structure $(S, +, \cdot)$ is a ring, with addition and multiplication inherited from R.

Example. The rings $n\mathbb{Z}$ for $n \in \mathbb{N}$ are all subrings of $\mathbb{Z}$.

Lemma 1.1. *Let S be a subring of R. Since $(R, +)$ is an abelian group, $(S, +)$ is a normal subgroup of $(R, +)$. Thus, we can make sense of the quotient group $(R/S, +)$.*

Lemma 1.2. *Let S be a subring of R. Then, the quotient $(R/S, +, \cdot)$ is a ring with multiplication $(a + S) \cdot (b + S) = ab + S$ if and only if $ab - xy \in S$ for all $a, b, x, y \in R$ such that the cosets $a + S = x + S$, $b + S = y + S$.*

Example. Consider the ring $\mathbb{Z}$ and the subring $n\mathbb{Z}$. Then, the quotient $\mathbb{Z}/n\mathbb{Z}$ is indeed a ring.

Example. Consider the ring $\mathbb{Q}$ and the subring $\mathbb{Z}$. It cal be shown that $\mathbb{Q}/\mathbb{Z}$ is not a ring under the 'natural' multiplication.

Definition 1.6. Let R be a ring and let I be a subset of R. We say that I is an ideal of R if $(I, +)$ is a subgroup of $(R, +)$, and $rx, xr \in I$ for all $r \in R$, $x \in I$.

Example. Consider the ring $\mathbb{Z}$, and the subring $n\mathbb{Z}$. This is an ideal of $\mathbb{Z}$, since $m(n\mathbb{Z}) \subseteq n\mathbb{Z}$. Indeed, every ideal of $\mathbb{Z}$ is of the form $n\mathbb{Z}$. This will follow from Euclid's Division Lemma.

Example. The subsets $\{0\}$ and R of any ring R are trivial ideals.

Lemma 1.3. *Let R be a ring, and I be an ideal of R. Then, the quotient R/I is a ring.*

Proof. Note that whenever $a - x \in I$, $b - y \in I$, we demand that $ab - xy \in I$. This can be rewritten as $(a - x)b + x(b - y) \in I$, which is clearly true by the properties of the ideal I. □

Definition 1.7. An ideal $I \subset R$ is called finitely generated if there exist $x_1, x_2, \ldots, x_n \in I$ such that every element of I can be written as a finite linear combination

$$x = r_1 x_1 + \cdots + r_n x_n,$$

where $r_i \in R$. We denote $I = (x_1, x_2, \cdots, x_n)$.

Definition 1.8. An ideal generated by a single element is called a principal ideal.

Example. Every ideal of $\mathbb{Z}$ is a principal ideal.

Definition 1.9. Let R be a ring and $a, b \in R$, $a, b \neq 0$. If $ab = 0$, we call a a left zero divisor and b a right zero divisor.

Example. Consider $2, 3 \in \mathbb{Z}/6\mathbb{Z}$; then $2 \cdot 3 = 6 \equiv 0$.

Definition 1.10. A commutative ring R is called an integral domain if it has no zero divisors.

Example. When p is prime, the rings $\mathbb{Z}/p\mathbb{Z}$ are integral domains. Note that this set is a group under both $+$ and $\cdot$.
